TITLE: Automatic calibrating gas-measuring devices |0

SOURCE: USSR. Komitet standartov, ser. 1 izmeritel'nykh priborov. Trudy* institutov Komiteta, no. 66 (126), 1962. Issledovaniya v oblasti izmereniy davleniya, raskhoda i vakuumu, 5-13

TOPIC TAGS: calibrating gas-measuring devices, continuous flow of gas

ABSTRACT: An experimental automatic calibrating gas-measuring device with 2 continuously operating measuring tanks was found to substantially increase the threshold value of "checking" consumption. It is a particularly valuable device when used for certain types of research in that a continuous flow of gas is involved. Further work is suggested in the study of the metrological characteristics of these devices in order to determine threshold input values for given measuring tank capacities and with regard to a choice of the most efficient types of automatic equipment. Kromlevskiy, P. P.

Flowmeters (Raskhodomery*), 2d ed., rev. and enl., Moscow, Mashgiz, 1963, 655 p., illus., biblio., Errata slip inserted. 8,000 copies printed.

TOPIC TAGS: flowmeter, tachometric flowmeter, electromagnetic flowmeter, ultrasonic flowmeter, calorimetric flowmeter, thermoanemometric flowmeter, ionization flowmeter, nuclear magnetic resonance flowmeter, partial flowmeter, spring differential manometer, compensation differential manometer, liquid differential manometer, floating differential manometer, bell differential manometer

PURPOSE AND COVERAGE: The book gives the theoretical bases and a critical analysis of the operation of industrial devices for measuring the consumption of a liquid, gas, or vapor. Meters of a variable drop in pressure, a variable level, flow (constant drop in pressure, floating, spring, vane), activated flow, tachometric, electromagnetic, ultrasonic, calorimetric, thermoanemometric, ionization, nuclear magnetic resonance, partial, and others are considered. The book is intended for engineers and technicians who design and use flowmeters.

TITLE: Dynamic characteristics of measuring instruments 14

SOURCE: Izmeritel'naya tekhnika, no. 2, 1966, 19-22

TOPIC TAGS: measuring instrument, measurement, *SCIENTIFIC STANDARD*

ABSTRACT: There has been no uniformity in criteria and terms used in various Soviet Standards for describing dynamic characteristics of measuring instruments. These terms and their definitions used in various Standards are cited: "thermo-couple inertness," "thermal inertia factor," "thermal inertia," "transient time," and "delay constant." Most Standards specify the "sluggishness time" as the only criterion for dynamic characteristics; this is acceptable if the transient

Card 1/2

UDC: 621.1/2.087.44

L 31976-66
ACC NR: AP6010866

process is describable by a first-order linear equation. Any, however complicated, measuring instrument can be approximately described by an n-order differential equation. Two quantities are recommended for evaluating the dynamic properties of an instrument: time constant T , and order of the equation n . The latter determines the initial, the most important, part of the transient response curve; the time constant characterizes the rest of the curve. It is theoretically proven that these two quantities adequately describe the dynamic properties of any aperiodic system, such as a thermoelectric pyrometer, thermometer, manometer, or impulse-tube differential manometer. TEXT: A description and calculation of the circuit of a direct current transistorized amplifier, executed as an attachment to the MNO-2 (MPO-2) oscillograph or to a pointer-type instrument, are given. The amplifier is assembled on PIA (PIA) triodes for the signal amplification from thermocouple within the range of 0-8 millivolts. The drift of the amplifier is 5 millivolt/hour. The amplifier is supplied from the network of 127 volts, 50 cycles. It is proposed to connect, instead of the usual capacitor, in the filter parallel to the load a transistor through which the variable component of the rectified voltage is

TITLE: New methods of realizing the thermodynamic scale
in the range of low temperatures

PERIODICAL: Referativnyy zhurnal, Elektrotehnika i energetika,
1961; No.6, pp.3-4, abstract 6G23. (Tr. in-tov Kom-ta
standartov mer i izmerit. priborov pri Sov. Min. SSSR,
1960, Issue 49, (109), 24-29)

TEXT: The paper deals with work on realizing a thermodynamic
scale at low temperatures by the method of an electroacoustic gas
thermometer and the method of counting thermal noise voltage pulses.
Realization of the thermodynamic temperature scale by means of the
electroacoustic gas thermometer is based on the dependence of the
temperature of the resonant frequency of the oscillations of the
sound wave in an acoustic tubular resonator. The realization by
means of a thermal noise thermometer is based on the temperature
dependence of the number of noise voltage pulses, the amplitude of
which exceeds a given discrimination threshold. In the applied
methods, measurement of the temperature is realized by means of

X

Card 1/2

frequency measuring instruments, as a result of which a high sensitivity is achieved which increases with decreasing temperature. Basic circuits are given for both systems and also the results of measuring the boiling temperature of hydrogen and oxygen. It is pointed out that although the obtained results are in good agreement with the data of the international temperature scale, they are preliminary, since the influence of systematic errors on the measured results has not been adequately studied. Work is continuing on improving the accuracy of the thermodynamic temperature scale in the range 4-273°K by means of the electroacoustic gas thermometer and the thermal noise thermometer methods and work is also continuing on stabilizing the temperature field and excluding systematic errors. 3 references.

"Variation of Bilirubin Fractionation Data in Jaundice."

Abstract. Ukrainian. Vol. 104, No. 11, 17 Mar 1967, pp. 10-12, 13, 14.

Abstract. [Abstracts' Russian summary modified] The authors report the results of large scale fractionated bilirubin determinations in jaundice of different etiology. The results presented are based on 100 clinically classified cases. In the progressive stage of the disease the ratio of serum bilirubin fractions is characteristic of the medical picture and reflect the basic state of equilibrium of the bile metabolism. The ratio of conjugation, the ratio of the fractions is determined by the degree of conjugation in efficiency which depends on the cause of jaundice and manifests itself mainly in the impairment of bilirubin conjugation. The conjugation coefficient shows a correlation with the degree of liver lesion. With the increase of the total bilirubin during recovery, the relative level of disconjugated increases. The regulation of bile conjugation is given as explanation by the authors, by means of, of course, various references.

Title : The Use of Poly-Operators.

Orig Pub : Studii si cercetari stiint. Acad. RPR. Baza Timisoara
Ser. 1, 1955, 2, No 1-4, 51-58

Abstract : The concept of the poly-operator, introduced by one of the authors earlier (Borneas, M., Studii si cercetari stiint. Acad. RPR, Baza Timisoara, 1953) are formulated in the following manner. The poly-operator \hat{B} is determined by the matrix B_{ik} , which satisfies the relation

$$(\hat{B} \psi)_i = \hat{B}_{ik} \psi_k, \text{ where } \psi_k = \psi(\underline{x}, t, s_k) \text{ are values}$$

Card 1/2

RUMANIA/Theoretical Physics

B-5

Abs Jour : Referat Zhur - Fizika, No 5, 1957, No 10877

assumed by the wave function $\psi(x, t, s)$ of a system with an internal degree of freedom s . Using this concept, the authors establish the poly-operator form of the Dirac equation, which differs substantially from the usual one in view of the diagonal nature of the momentum poly-operator

$$\hat{p}_\mu.$$

Next, the authors find the poly-equation for a particle with negative mass and calculate the energy of the non-relativistic magnetic electron in an external magnetic field. In conclusion, considerations that relate the method of poly-operators with the method of associated matrices are raised.

✓ The distribution law of ferromagnetic domains according to the "coercive field" criterion in a phenomenon of irreversible magnetization (phenomenon of Procopiu). B. Rothenstein and I. Kremer (Polytech. Inst., Timisoara, Romania). Acad. rep. populare Romane, Baza cercetari stiinf. Timisoara, Studii cercetari, stiinf., Ser. stiinte chim. 6, No. 1-2, 157-63 (1959).—The phenomenon of Procopiu is observed when a ferromagnetic sample is placed in a continuous magnetic field of const. intensity, on which is superimposed an alternating magnetic field. If the amplitude of the latter is increased continuously up to a specific value and then decreased continuously to 0, the sample exhibits a residual magnetism in the direction of the continuous field. The residual magnetism depends on the effective intensity of the alternating field. The Procopiu phenomenon is due to the irreversible displacement of the Bloch walls under the influence of the magnetic fields, and is a consequence of the gaussian distribution law of ferromagnetic domains according to the "coercive field" criterion. TITLE: Complexometric determination of the Ca and Mg content of bile

SOURCE: Kiserletes Orvostudomany, v. 17, no. 1, 1965, 98-100

TOPIC TAGS: digestive system, biochemistry, analytic chemistry

ABSTRACT: A rapid and accurate complexometric method is described for the determination of Ca and Mg ions in the bile and intestinal content. The method consists of a decomposition of interfering bile pigments with a base and their removal with chloroform. Following this, the Ca and Mg ions can be measured by complexometry. TOPIC TAGS: magnetometer, aerial magnetic surveying/AM-13

TRANSLATION: A brief report is presented of experimental work with the AM-13 aeromagnetometer, carried out in 1960--1961 by the aeromagnetic party of Uzbekskiy geofizicheskiy trest (Uzbek Geophysical Trust). The investigations have shown that in order to exclude the deviation noise it is advantageous to do the measurements with a

gondola cable 20--25 meters long. A connection is established between the variational curve δT and the null-drift curve. It is shown that if δT of the variations is correctly taken into account, it is possible to plot the magnetic field relative to the control route without using reference and secant routes. A. "A Method of Determining Energy Dissipation in Elastic Vibrations," *Termicheskaya obrabotka i prochnost' metallov i splavov; sbornik statey* (Heat Treatment and Strength of Metals and Alloys; Collection Articles) Moscow, Mashgiz, 1958, 177 p.

A new method is proposed for determining the energy dissipation in the vibrations of a specimen fixed at one end in a test stand designed by S. O. TSORKALLO. The method is based on the determination of the path of motion of the specimen. The authors obtain equations that give the relationship between the elastic energy stored in the specimen, the amplitude of vibrations, the amount of energy dissipated, and the damping factor. The equations further account for the magnitude of working stresses imposed on the specimens and also determine energy dissipation per cycle, which is not obtainable ordinarily with the damping factor alone. These considerations, when applied to N36KhTYu steel, show that dissipated energy per cycle as a function of stress loading rises with increased stress, which is explained as the effect of microplastic deformation. At the same time, the higher the resistance of the metal to small plastic deformations, i. e., the higher the elastic limit, the smaller the dissipation increment. In particular, minimum values for the dissipation increment and its rate of increase are observed in specimens tested after hardening from a temperature of 950°C. and aging to 700°C for 2 hours, when their elastic limit is at its maximum.

TITLE: The effect of small additions of titanium and nitrogen on the properties of high-speed cutting steel

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Chernaya metallurgiya, no. 9, 1961, 129 - 137

TEXT: The main problem in producing the standard P18 (R18) and p9 (R9) high-speed cutting steels is to attain uniform distribution of carbides on which the uniformity of the grain size depends. Satisfactory distribution of carbides can be ensured by reducing the tungsten and chromium content so as to reduce the proportion of free carbides without decreasing the quantity of these elements in the solid solution. Steels of this type, however, show a tendency to excessive grain growth. This effect can be prevented by increasing the V content to 2 - 2.5%; in this case, however, steel becomes difficult to grind, which causes considerable difficulties in the fabrication of tools of complex shape. The object of the present investigation was to study the possibility of overcoming these

Card 1/0 1

The effect of

S/148/61/000/009/010/012
E193/E383

difficulties by the addition of elements which would inhibit grain growth of steel during pre-hardening heating without increasing the free-carbide content. Ti (a carbide-forming element) and N, which forms stable nitrides, were used for this purpose. The chemical analysis of the experimental alloys is given in a table. The maximum quantity of N was 0.01 - 0.02 - 0.03%. Several conclusions were reached.

1) Addition of 0.1 - 0.2% Ti or 0.02 - 0.03% N with 0.1 - 0.2% Al inhibits grain growth of medium-tungsten content, high-speed cutting steel, decreases its sensitivity to overheating and increases its strength.

2) The effect of Ti as a grain refining and strengthening addition is more pronounced than that of nitrogen. In Fig. 3, constructed for specimens quenched from various temperatures and tempered (three times) for 1 hour at 550 °C, the bending strength (σ , kg/mm²) is plotted against the quenching temperature (°C). Curves 2 and 1 relating, respectively, to steel without Ti and with 0.26% Ti. In fig. 7 (constructed for similarly heat-treated specimens) σ is plotted against the quenching

Card 2/6 4

The effect of

E193/E385

temperature ($^{\circ}\text{C}$), Curves 1 and 2 relating, respectively, to steel containing Ti and N additions.

3) The proportion of residual austenite unaffected by addition of N is decreased by the addition of Ti to an extent, illustrated in Fig. 4a, where the proportion of residual austenite (A, %) is plotted against the hardness temperature ($^{\circ}\text{C}$) for steel containing 3% Cr and no Ti (top curve), steel with 3% Cr and 0.26% Ti (dotted curve with an inflection point), steel with 2.68% Cr and no Ti (horizontal dotted curve) and steel with 2.67% Cr and 0.16% Ti (bottom curve).

4) The quantity of residual austenite in a hardened steel depends not only on the composition of austenite but also on its grain size attained during heating prior to hardening. With increasing grain size the stability of austenite increases and so does the quantity of residual austenite. It is for this reason that the proportion of residual austenite is reduced in the presence of Ti but is not affected by additions of N. ✓

AUTHORS: Geller, Yu.A., Kremnev, L.S.
TITLE: The effect of chromium on the properties of high-speed cutting steel
PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya metallurgiya, no.11, 1961, 129-136
TEXT: There is evidence that chromium has an appreciable effect on the working and properties of high-speed steel. The chromium content of such steels is fixed within the same range (4 to 4.5%) in the USSR and abroad for all grades, irrespective of wide variations in tungsten, molybdenum and vanadium concentrations. Work reported on the effect of chromium on the cutting properties (Ref.2: H. Peltzgutter. Stahl u. Eisen, H. 12, 1924) and hardenability (Ref.4: E. Gudremon. Special steels. v.11, Metallurgizdat, 1959) or on the phase composition (Ref.6: N.T.Chebotarev, Izv. AN SSSR, Seriya fizicheskaya, no.1, 1951; Ref.8: F.Kaiser, M.Cohen, Metal Progress, no.6, 1952) does not fully represent the influence of this element. Nor does it enable the optimum chromium content to be found for various contents of other elements, especially tungsten. To study this problem, the Card 1/4

The effect of chromium ...

S/148/61/000/011/010/018

authors investigated steels with 3.63 to 18% W, up to 4.2% Cr, 0.72 to 0.88% C and 1.0 to 1.7% V. These were induction melted, cast into 12 kg ingots and forged into 12 x 12 mm bars. After various heat treatments, phase analysis, solid-solution analysis, hardness measurements and determination of cutting properties and carbide distribution were carried out. The authors draw the following conclusions. In high-speed steel, chromium affects various transformations taking place during hardening and heat treatment, its influence is therefore very complex. Its main effect is on high-temperature transformations preceding quenching. As it is present in the form of a complex tungsten carbide, it lowers the solubility of this carbide in the austenite; the higher the chromium content in the carbide (and therefore in the steel), the greater the effect. Steels with less than 8 to 10% tungsten, in which grain growth begins at lower temperatures, require more chromium to obtain saturation of the solid solution with tungsten while keeping the grain small. The tungsten carbides precipitated on tempering form in larger quantities at lower temperatures and also coagulate at a somewhat reduced heating temperature if they contain more chromium. It is for

Card 2/4

The effect of chromium ...

S/148/61/000/011/010/018
E111/E480

this reason that, in steels with up to 8 - 10% W, the secondary hardness is raised but red hardness is reduced by chromium. Chromium hinders the transformation of the complex tungsten carbide into the simpler one insoluble in austenite. However, it increases carbide heterogeneity in steel with a higher carbide content (more tungsten) and this impairs strength. At the same time, chromium improves hardenability because it promotes a fuller solution of tungsten carbides and the formation of chromium carbides which go into solid solution on heating to 1100 - 1150°C. For improving the properties of high-speed cutting steel, the chromium content should be fixed in relation to that of tungsten. With up to 10% W, about 4% Cr is required to saturate the solid solution at lower temperatures, thus keeping the grains small, and to obtain a high secondary hardness. In steels containing over 10 to 12% W, the chromium content should be reduced to 3% in order to retain a fine grain size on high-temperature heating and to reduce carbide heterogeneity, increase strength and red hardness. There are 8 figures, 2 tables and 11 references: 8 Soviet-bloc and 3 non-Soviet-bloc. The two references to English language publications read as follows: Ref.1: P. Malkiewicz. Journ. Iron Card 3/4

AUTHORS: Kremnev, L. S. (Moscow); Gellor, Yu. A. (Moscow)

TITLE: Tungsten effect on the properties of high speed steels

SOURCE: AN SSSR. Izv. Metallurgiya i gornoye delo, no. 1, 1964, 136-142

TOPIC TAGS: steel, high-speed steel, tungsten, vanadium, WV steel, steel grain size, carbide phase in steel, WV effect on carbide, M_6C content in steel, VC content in steel, P18 high speed steel

ABSTRACT: Experiments were performed to study the effect of tungsten on the properties of high-speed steels, particularly its effect on the grain size and on the quantity of carbide phase. The samples contained 4-18% W. It was established that the steel properties do not bear a direct linear relation to W content. There were two characteristic W concentrations in steels; one of 12-13%, the other of 7-8% (at 1.5% vanadium). Steels with 12-13% W contained a carbide phase M_6C rich in W in the presence of vanadium; steels with 18% W and free of vanadium also contained this phase. The increase in W content from 12 to 18% did not change substantially the quantity of M_6C . Experiments showed that the greatest ..

Corr/2

ACCESSION NR: AP4019814

quantity of vanadium was dissolved in M_6C of the 12-13%W steels in which the quantity of solid vanadium carbide VC was small. For this reason hot strength of vanadium-bearing high-speed steels reaches its maximum at 12-13% of W concentration. The technical properties of steel containing 12-13% W and 1.5-1.9% of V did not differ from those of the common P18 steel. Tungsten concentration of 7-8% was the necessary minimum for achieving the secondary hardness in high-speed steels. Steel of this type may be used as a substitute for P18 steel in producing cutting tools for work under light cutting loads. Orig. art. has: 1 table and 6 figures.

Emulsification of mercury. L. Ya. Kremnev. *J. Phys. Chem.* (U. S. S. R.) 5, 1651-61(1934); cf. C. A. 28, 4967. — Suspensions of oxides and some slightly sol. solids stabilize the Hg spheres (globules) by forming firm protecting layers. Emulsification by suspensions is usually accompanied by the formation of gelatinized emulsions. Either typical hydrophilic substances or strongly hydrated inorg. colloids emulsify Hg under a sufficiently high concn. of the latter forming firm protecting films. From molecularly dispersed substances oxidizing chlorides, O-contg. and other oxidizers emulsify Hg. Strictly speaking, in such a suspension Hg_2Cl_2 and Hg_2O are the emulsifiers, formed through the oxidation of Hg. The conditions of stabilization of dil. and concd. emulsions in water are compared. Results are reported for the oxides or hydroxides of Ca, Mg, Ba, Zn, Hg, Pb, Cu, Fe and Si and on Hg_2Cl_2 , HgI_2 , $HgBr_2$, $ZnCO_3$, $PbSO_4$, $BiONO_3$, HgS with various electrolytes. Stabilization was effected with Prussian blue, Congo red, Night blue, benzopurpurin-4 B, benzopurpurin-10 B and chrysophenin. R. H.

4988. Classification of Emulsions. A. Habinerson and L. Kravtsov. *Acta Physicochimica*, 8. 1. pp. 108-110, 1934. In German.—
 Emulsions as regards their material composition are divisible into three groups: (A) oil in water, (B) water in oil, and (C) fluid metal in water or other fluid. They are also divisible into: (a) dilute, (b) concentrated, and (c) foam-like. Metallic emulsions (C) are stabilized in the same way as (A) and (B); apparent differences are discussed. Foams (c) do not represent a disperse system in the ordinary sense; their stability is solely due to that of the lamellar framework of the foam. [See Abstract 2093 (1934).] C. A. S.

Hydroscopic properties of aqueous solutions of sodium oleate. In Ye. Kremnev and Yu. O. Kharina. *Trudy LKKKhT (Lab. Kolloidnoi Khim.)* 1930, No. 7, 85-92; *Khim. Refert. Zhur.* 2, No. 6, 18(1939).—The soly. of alcs. of the aliphatic series (amyl and octyl) in water contg. Na oleate increases considerably with an increase of the concn. of Na oleate. The lower homologs (including amyl alc.) cause no structure formations in aq. solns. of Na oleate, whereas the higher alcs. (octyl), even in small concns., increase considerably the structural η of the system. The formation of these structures is explained by the interaction of the mols. of oleate and alc.

<p>Gelatinized emulsions. IV. Limiting thickness of the stabilizing layer. I. Ya. Krut'nyy and S. A. Noskin (Leningrad Chem. Tech. Inst.). <i>J. Gen. Chem.</i> (U.S.S.R.) 16, 2000-5 (1948) (in Russian); cf. <i>C.A.B.</i> 20, 2072P, 5482P; 34, 2230P. Benzene was emulsified by shaking 5% aq. Na oleate soln. with successive portions until a new addn. of CaCl_2 would have rendered the emulsion unstable; the limiting ("gelatinized") emulsions thus obtained are characterized by the "emulsifying capacity" $\sigma_m = \text{max. vol. of the disperse phase (CaCl}_2\text{) per 1 ml. of Na oleate soln.}$ From microscopic measurements of the vol. v_1 and the surface area F of the dispersed droplets, the thickness δ of the water sheath around the droplets was found by $\delta = \sigma_m / F$, where $\sigma_m = \text{ratio of the vol. of the emulsifying soln. and that, } v_1, \text{ of the disperse phase; in all limiting emulsions, } \delta \text{ was found to have approx. the same value, } \delta = 3.01 \mu; \text{ this is the same order of magnitude as the upper limit of the range of orienting surface forces in a free film of fused paraffin inhibiting the coalescence of Hg droplets (cf. Berdennikov, et al., C.A.B. 20, 2002P). The limiting } \sigma_m \text{ varies according to the method of emulsification; depending on whether the emulsion was prepd. by (I) sharp violent shaking after each addn. of } \text{CaCl}_2, \text{ (II) regular, more uniform shaking, (III) perfectly uniform motion, } \sigma_m \text{ was } = 100, 100, 205 \text{ ml., resp.; the droplet-size distribution curves were likewise different according to the method of emulsification, the dispersity decreasing from I to III. However, the total surface area } S_m \text{ of the droplets, identical with the limiting max. surface area developed by 1 ml. of the emulsifying soln., was const. } = 10^8 \text{ sq. cm., corresponding to } \delta = 10^{-6} \text{ cm. Emulsification by the 3 methods to the same const. } \sigma_m = 100, \text{ resulted in } \delta = 0.010, 0.018, 0.024 \mu, \text{ resp.; the two latter emulsions could be dispersed still further by supplementary shaking, whereas the 1st, having attained the min. } \delta, \text{ could not. A limiting emulsion changes spontaneously on standing in the direction of increase of } \delta \text{ and decrease of } S; \text{ within 24 hrs., a } \sigma_m = 100 \text{ emulsion changed from } \delta = 0.01 \text{ to } 0.025 \mu \text{ and from } S = 1 \times 10^8 \text{ to } 0.4 \times 10^8 \text{ sq. cm. If all of the Na oleate is coed. (adsorbed) on the benzene-water interface in a unimol. layer, the area per mol. (in a 5\% soln.) } = 100 \text{ sq. A.}$</p>

COMMON ELEMENTS	COMMON ELEMENTS	<p><i>*Causes of Metal Dispersion in the Electrolytic Magnesium Process. L. Ya. Krimm, A. I. Peklinov, and K. P. Miahchenko (Tsvet. Metall., 1946, 19, (6), 51-54; C. Abz., 1947, 41, 3378).—[In Russian]. In the electrolytic magnesium process small globules of magnesium are formed which separate out together with MgO and other impurities. It was proved experimentally that the magnesium globules form a dispersion in the molten chloride electrolyte. The dispersion is stabilized and the coalescence of the globules hindered by films of MgO enveloping the globules. The MgO is formed by contact of the metal with H₂O or with O₂. The H₂O is introduced by the salts of the electrolyte. Drying the salts (NaCl and KCl) partially eliminated the H₂O but not the O₂ from the air. The latter was absorbed by graphite rods placed in the bomb in which the experiments were carried out. With these two precautions, dry salts and graphite to fix the O₂, no metal globules formed. Fe₂O₃ and Na₂SO₄ also dispersed the metal, the former by adhering to magnesium and the latter by oxidizing magnesium to MgO. The dispersion of the metal was prevented by NaF and CaF₂. The breaking up of the dispersion lies in the ability of these compounds to dissolve MgO. Of the fluorides, NaF is more effective. Surface-tension measurements of KCl, NaCl, MgO, MgCl₂, and their various combinations, made at 850-860° C., contradict the opinion that surface tension is the main factor in "magnesium rue" formation.</i></p>	COMMON ELEMENTS

PROCESSES AND PROPERTIES INDEX																																																			
<p><i>*Emulsions of Metallic Magnesium in the Melts of Some Salts. L. Ya. Karginov, K. P. Mashchenko, and A. I. Keklinov (Zhur. Priklad. Khim., 1946, 19, 363-370; C. Abs., 1947, 41, 1140).—[In Russian]. Magnesium forms emulsions in melts of sodium chloride, potassium chloride, and carnallite; the emulsions are of the metal electrolyte type. The basic stabilizing effect on the emulsion is produced by magnesium oxide, either formed by oxidation or introduced artificially; stabilization is also achieved by iron oxide and sodium sulphate. Sodium and calcium fluorides are de-emulsifiers, probably because of solution of the protective film of magnesium oxide in the particles of the metal. Ferro-silicon and silica also prevent emulsion formation. The surface tension was measured at the interface of magnesium and the various melts of potassium chloride, sodium chloride, and magnesium chloride, with and without added magnesium oxide, barium chloride, or calcium fluoride. All values lay between 319 and 384 ergs/cm.² at 850–860° C. in an argon atmosphere.</i></p>

Gelatinized emulsions. V. Emulsifying ability of aqueous solutions of sodium oleate and gelatin. L. Ya. Kremer and H. A. Roskin (*Engineering Technol. Inst. - ~~Journal~~ Zhur. V. 255-70 (1947).*—The emulsifying ability A of a substance cannot be judged from the max. vol. V_m of C_{18} , which can be emulsified by 1 cc. of the emulsifier soln., as V_m depends on the intensity of agitation (V_m is greater, the weaker is the shaking). The max. area S_m or the min. thickness δ of the stabilizing layer is a true measure of A ; they did not vary when, because of varying agitation, V_m varied as 1:2.6; Na oleate (I) was the emulsifier. When I concn. c increased from 1% to 5%, 10%, and 15%, S_m was 33, 100, 100, and 110×10^4 sq. cm.; thus S_m and hence δ were independent of c at high c . The area δ occupied by 1 mol. I was 160 sq. A. at $c = 1\%$; thus, dil. monolayers were efficient emulsifiers. The dispersity of the emulsions slightly increased with c , but the most frequent particle diam. remained near 1μ . The vol. of C_{18} that can be emulsified by 1 g. I was 3.3, 2.8, and 1.41 at $c = 1, 5$, and 15%; thus dil. solns. of I were better utilized. Photographic gelatin as emulsifier gave S_m of 12×10^4 sq. cm. at $c = 0.5$ and 1%; thus A of gelatin was $1/4$ th the A of I. J. J. B.

Fundamental principles of formation of concentrated emulsions of high stability. L. Ya. Kromann. *Kolloid. Zhur.* 10, 18-23 (1948). — (1) Highly stable concd. emulsions of $\text{C}_{12}\text{H}_{26}$ in H_2O are obtained by the use of thixotropic mists of aliphatic alcs. and Na oleate, owing to their capacity of rapid restoration of the structures perturbed in the process of emulsification. With the alc. introduced either into the $\text{C}_{12}\text{H}_{26}$, or into the 1% Na oleate soln., the stability of the emulsion increases with the length of the chain of the alc. (BuOH , AmOH , octyl, and cetyl alc.), and with the concn. of the alc. Addn. of ~0.1% cetyl alc. to 1% Na oleate is enough to ensure very long stability of a 60 vol. % $\text{C}_{12}\text{H}_{26}$ emulsion, and with a greater amt. the stability is practically indefinite, in contradiction to the observations of Schulman and Cockbain (*C.A.* 23, 2140').

(2) Thixotropy of the cetyl alc. + 1% Na oleate mists was stud. by the degree of reproducibility of the "zero point," i.e. of the viscosity at the lowest pressures p. repeated measurements under increasing pressures p. By measurements of the relative viscosity η/η_0 (subscript 0 referring to H_2O) as a function of p. at different concns. c of the cetyl alc., the initial anomalous (structural) η is higher the greater c; below $c = 0.1\%$, structure formation is wholly absent; up to 1% it is destroyed fairly rapidly, whereas it remains stable at higher c. The thixotropy of the Na oleate + cetyl alc. emulsifier is preserved in the concd. $\text{C}_{12}\text{H}_{26}$ emulsion, which also shows thixotropic behavior of η . The anomalous (structural) branch of the η/p (p) curve of both the Na oleate + cetyl alc. mixt. and of the stabilized $\text{C}_{12}\text{H}_{26}$ emulsion becomes increasingly pronounced as the temp. decreases. (3) With increasing concn., the surface tension of equilconc'd. sols. of Na oleate + cetyl alc. falls more rapidly and below that of pure Na oleate sols. of the same concn., owing to the surface activity of the cetyl alc.

"Gelatinized Emulsions: VI, The Quantitative
Emulsified Nature of Oleates of Sodium, Calcium,
Rubidium and Cesium," L. Ya. Krenner, R. N. Kagan,
Chair of Colloid Chem, Leningrad Technol Inst
Imeni Lomonosov, 4 1/2 pp

"Toloid Zhur" Vol X, No 6 - p.436-40

Study determines the critical width of protective
water layers in saturated, concentrated emulsions
stabilized by oleates of sodium, calcium, rubidium,
and cesium. Establishes the emulsive capacity of
alkali oleates by determining the maximum sur-
face S₀ generated by one cm² of stabilizer
solution during the formation of such emulsions.
Boys are located in the following series (the
emulsive capacity of sodium oleate being used
as unity): Oleates Na: K: Rb: Cs = 1: 2:
2.83: 5.0. Submitted 2 Oct 47.

<p>Ostwaldized emulsions. VII. Strength of stabilizing layers. The role of the free stabilizer solution. 1. Ya. Kremnev and S. A. Beskin. <i>Kolloid. Zhur.</i> 11, 24-9 (1949); <i>Ch. C. N.</i> 41, 67911. —Concd. emulsions of benzene in 5% Na oleate soln. were forced through a sintered glass filter. The rate $-dm/dt$ of the decrease of the amt. m emulsified increased when the distance l between the droplets (calcd. from their concn.) decreased according to $(dm/dt)_{(2l \rightarrow 24)} = \text{const.}$, l & being 0.02 μ, between $2l = 0.03 \mu$ and 0.12 μ. Stability increases with l because free stabilizer soln. can repair damaged stabilizing membranes and acts as lubricant for slipping of droplets past one another. The lubricating effect of stabilizer is shown also by expts. in which a glass sphere partly filled with Hg descended in the emulsions. The time of descent $\tau = \text{const.}$ ($2l \rightarrow 24$).</p> <p>J. J. Bikerman</p>

Olefinated emulsions. VIII. Stabilization of oil in water and water-in-oil emulsions of the limiting concentration by triethanolamine oleate. Structure of protective adsorption-solvation layers in emulsions. L. Ya. Kuznetsov and N. I. Kufkina (Technol. Inst., Leningrad). *Kolloid. Zhur.* 13, 38-45 (1951); cf. C.A. 45, 7775t. $-(HOCH_2CH_2)_3N$ oleate (I) can stabilize both oil-in-water and water-in-oil emulsions. The maximally concd. emulsions of C_{18} in 0.23-0.31 M aq. I had the film thickness δ of 100 Å., corresponding to 50-70 sq. Å. for each mol.; thus, the protective monolayer was rather dil. The emulsion in 0.22 M aq. $(HOCH_2CH_2)_3N$ stearate had $\delta = 110$ Å., i.e. 68 sq. Å./mol.; this showed that the double bond in the oleate has no significant effect on emulsifying action. Aq. $(NH_4)_2CO_3$ solns. (concns. not specified) can be emulsified in I solns. in C_{18} or toluene. In these emulsions, δ was as low as 20 Å., corresponding to, e.g., 130 sq. Å./mol. These emulsions were stiff and consisted of bubbles mainly of 1 μ diam. Emulsions of aq. salt solns. (not of H_2O) in oil are stabilized by I, because the distribution of I between H_2O and C_{18} is shifted toward C_{18} by salts. Thus, the amt. of I extd. by C_{18} from an aq. soln. is increased, e.g., from 0.3 to 0.7 by 1.5 M $(NH_4)_2CO_3$ and KCl, to 0.8 by 1.5 M Na_2SO_4 , to 0.8 by 1.5 M KI, and 0.9 by 1.5 M NaI. The emulsifier mols., which are immersed partly in the aq. and partly in the oil phase, act like rivets. J. J. Bikerman

Homogenization of emulsions by pressing through capillaries under low pressures. L. V. Kurnikova and A. S. Koryak (Leningrad Technical Inst., *Plasticheskiy Abraziv*, 1953, No. 1, 10-11, 621 (1953)). The authors examined the effect of 10, 20, and 50% emulsions of $C_{10}H_8$ in a 5% solution of Na oleate, pressed through capillaries 0.2-100 cm. long, diam. 0.2-1.2 mm., under pressures not exceeding 5 atm., increases linearly with the flow velocity v . In 10 and 20% emulsions, the straight line passes through the origin, and its slope increases strongly with the concn. of the emulsion. In a 50% emulsion, the increase of s with v is much slower, and the emulsion does not pass through the origin. With the 100% emulsion, with a capillary of given dimensions and under a constant pressure, the value of s after homogenization of the disperse phase markedly with decreasing viscosity of the disperse phase (mixtures of $C_{10}H_8$ and petrolatum). Under the same conditions, the increase of s after pressing through the capillary is determined by the nature of the stabilizer, decreasing in the order, Na oleate, saponin, gum arabic, gelatin. Photomicrographic examination showed the flow to be turbulent even at very low velocities of flow (8 cm./sec.). N. Thon

Gelatinized emulsions. X. Homogenization in capillaries. *Ac. Ya. Kreiniev and V. S. Kuprik (Leningrad Techn. Inst. B. Khim. Zh. 14, 98-102 (1952); cf. C.A. 43, 7775h, 40, 237h.*—Emulsions of $C_{12}H_{26}$ (90-97.6 vol. % in aq. 3% Na oleate soln. (2.4-20%) became less polydisperse after passage through a capillary under pressure. The most frequent particle diam. remained const. (about 1μ), but the max. frequency increased, e.g., twofold. The sp. surface S increased, e.g., from 500 sq. cm./cc. to 2500 when an emulsion was pressed through a capillary at the rate v of 1 cm./sec.; this increase depended on v only and was independent of the length (25-100 cm.) and the diam. (0.36-1.48 mm.) of the capillary, and of the pressure (0.3-4.5 atm.). The increase of S was for 90% emulsions greater (e.g., twice as great) than for 94% emulsions. If, instead of $C_{12}H_{26}$, mixts. of $C_{12}H_{26}$ and liquid paraffin (I) were used as the internal phase, the effect of the passage through a capillary was greater, the higher the percentage of $C_{12}H_{26}$ (i.e. the smaller the viscosity); thus, S was increased from 250 to 718 in I and from 250 to 3150 in $C_{12}H_{26}$. Emulsions stabilized with saponin, gum arabic, or gelatin behaved similarly.

1976. Conditions of the spontaneous disintegration of drops during emulsification. L. YA. KREINER AND A. A. RAVDEL. Dokl. Akad. Nauk SSSR, 240, No. 3, 415-7 (1975) In Russian.

According to Reblinder [Kolloidnyi Zhurnal, 8, 157 (1946)], the dispersion of the disperse phase of an emulsion is effected by the spontaneous disintegration of drops which are stretched beyond a certain critical ratio $h/a = 2\pi$, where h is the height and r the radius of the base of the liquid cylinder. Mathematical analysis shows that, irrespective of the relative radii of the two resultant drops, the least favourable conditions for disintegration are when the ratio ES_1/S_2 (the sum of surfaces of the resultant drops, divided by the surface of the cylinder) equals 2. Values below 2 favour the disintegration much more than those above 2. Hence the unstable condition of the cylindrical drop can be attained at small compression values. Finally, the disintegration occurs more readily for large values of the ratio ES_1/S_2 than for the smaller ones.

✓ The limiting dimensions of the droplets in an emulsion. A. A. Ravelet and L. Ya. Kremnev (Leningrad Technol. Inst., Leningrad). *Doklady Akad. Nauk S.S.S.R.* 90, 599-602 (1953).—Coalescence of the droplets in an emulsion made mechanically of pure liquids, follows Smolukhovskii's equation: $\varphi - \varphi_0 = K\tau_K$, where φ_0 and φ are the initial and final volumes, resp., of a droplet; τ_K is time, and K is the velocity const. of coagulation. $K = (4/3)\pi kT/\eta$, where k is the Boltzmann const., T is abs. temp., and η is the viscosity of the dispersing medium (water). For a concd. emulsion of benzene in water at room temp., $K = 5.5 \times 10^{-11}$ cc./sec., and $\tau_K = 1.8 \times 10^{11}(\varphi - \varphi_0)$ sec. For droplets of radii 0.1, 1.0, 10, and 100 μ (the volumes are 3.3×10^{-14} , 3.3×10^{-12} , 3.3×10^{-10} , and 3.3×10^{-8} cc./droplet), τ_K , the time for the vol. to increase 1000 times (by coalescence) is: 6×10^{-4} , 0.6, 6×10^3 , and 6×10^6 sec., resp. For an emulsion contg. a surface-active stabilizer, such as soap, the authors derive an equation for τ_p , starting with the Gibbs-Thomson equation for the adsorbed surface layer on the droplets. Their final equation is $\tau_p = (RT\sigma/6\pi MCD_s)(r_0^3 - r^3)$. For benzene and water, the surface tension σ is 35 dynes/cm., C_s , the satd. concn. in the vol. of the dispersing medium is 7×10^{-4} g./cc. at $T = 298^\circ$, the coeff. of diffusion D of benzene into water is taken as 1 sq. cm./day. M and δ are the mol. wt. and d. of the disperse phase. With these values, $\tau_p = 1.38 \times 10^4(r_0^3 - r^3)$ days. When $r = 0.1 r_0$, this formula gives the time taken for the droplet to decrease in size by 0.1 r_0 . This decrease is caused by diffusion, (which is taken as equiv. to the isothermal distn. of the droplets) which goes on even as the emulsion ages, with an eventual coarsening of the larger droplets. The above equation, when r_0 is 0.1, 1, 5, and 10 μ , yields τ_p , 0.12 sec., 1 min., 4 hrs. 10 min., and 1.38 days, resp. In other words, there are 2 ways by which emulsified droplets increase in size: (1) by coalescence, which, however, is hindered when a stabilizer covers the surface of the droplets, and (2) by aging of the emulsion, which is usually observed.

The mechanism of emulsification. L. Ya. Kremnev and A. A. Ruvdel (Leningrad, Technol. Inst., Leningrad). *Kolloid. Zhur.* 10, 17-28 (1951); *cf. C.A.* 46, 1611b. A liquid cylinder (whose ratio of height to radius is k) spontaneously breaks into 2 spherical drops (whose radii are in the ratio $n:1$) when the total surface area of the drops is smaller than that of the cylinder, i.e. when $\beta = [2(n^2 + 1)/(1 + k)]^{1/2} [3k/4(n^2 + 1)]^{1/2}$ is greater than 1. The drop formation is least probable when $k = 2$ and when $n = 1$; its probability is almost independent of n when $n < 0.2$ or $n > 5$. An ellipsoid (with axis ratio k) spontaneously gives 2 drops when $(n^2 + 1)/[(n^2 + 1)^{1/2} K^{1/2}] > 1$ for prolate and $(n^2 + 1)K^{1/2}/(n^2 + 1)^{1/2} > 1$ for oblate shape. Equations are given also for breakdown of an ellipsoid into many droplets and for successive separ. of many small droplets from an ellipsoid. The inverse process of coalescence of small drops follows the Smoluchowsky theory; when the droplets are less than about 1μ in diam., their coalescence is more rapid than their formation; thus usual emulsions, both stabilized and unstabilized, contain chiefly particles of about 1μ . The aging of emulsions is due partly to soln. of small, and growth of large, particles; the time for particle radius r_0 to decrease to r is $RT\delta^2(r_0^3 - r^3)/6\sigma MDr$; δ , M , and c are d., mol. wt., and soly. of the disperse phase; σ = interfacial tension, and D = diffusion coeff. Phase Inversion in emulsions. L. Ya. Kremnev and N. I. Kulshina. *Kolloid. Zh.* 17, 31-3, 1955, 17, 31-3 (1955) (English translation); cf. preceding abstr. When to an oil-in-water emulsion of equal vols. of $C_{18}H_{36}$ and 0.3M aq. soln. of Na oleate, NH_4 oleate, or $(HOOC)_2H_{17}N$ oleate increasing amts., c , of dry $NaCl$, Na_2SO_4 , Na_2CO_3 , NH_4Cl , $(NH_4)_2SO_4$, or $(NH_4)_2CO_3$ were added, the emulsion was broken at c of about 0.25 mole/l. At a slightly greater c (about 0.3 mole/l.) phase inversion occurred, and the resulting water-in-oil emulsion was stable; it could be broken by add'n. of H_2O . In the absence of foreign salts, the hydrophilic end of the emulsifier is more solvated by H_2O than the hydrophobic end is by $C_{18}H_{36}$; hence water is the continuous phase. Foreign salts "dehydrate" the hydrophilic part, and its solvation becomes less than that of the hydrophobic radical; hence, $C_{18}H_{36}$ becomes the continuous phase. The degree of solvation can be judged from the crit. thickness of the films of the continuous phase in emulsions of limit concn.; if this thickness is greater for the aq. than for the oil phase, H_2O is the continuous phase; otherwise, H_2O forms droplets. Title : Nature of Aging of Highly Concentrated Emulsions

Orig Pub : Dokl. AN SSSR, 1956, 109, No 6, 1152-1155

Abstract : The prolonged aging of highly concentrated converse emulsions (E) of the v/m type stabilized by NH_4 , Na and triethanolamine oleates was investigated. First, the dispersed liquid begins to separate from the E surface as an unbroken layer, and after a prolonged time the system falls completely to pieces. The drops (D) increase simultaneously in size. In the authors' opinion, the drop of the dispersion degree is caused by the isothermal distillation (ID) of tiny drops (RZhKhim, 1954, 33982) through the thin adsorption-solvate layers separating them from the neighboring drops of a larger size. At this occasion the protection layers break through in the result of their curvature change and of the rise of the Laplace pressure in the process of ID. The large drops on the emulsion
